

Links between Dissolved Organic Carbon export and terrestrial primary productivity: implications for controls on the latter

Don Monteith

UK upland DOC concentrations: increasing over past 3 decades

Rate of change in DOC \propto rate of change in acid deposition

e.g.

- “DOC exported from C-rich landscapes appears younger than the soil C itself, much of it comprising C assimilated post-1950s.”

Evans et al. Geophys Res Lett 34, 2007.

- “peat-derived DOM is 5 years old on average, with most of it very recently formed.”

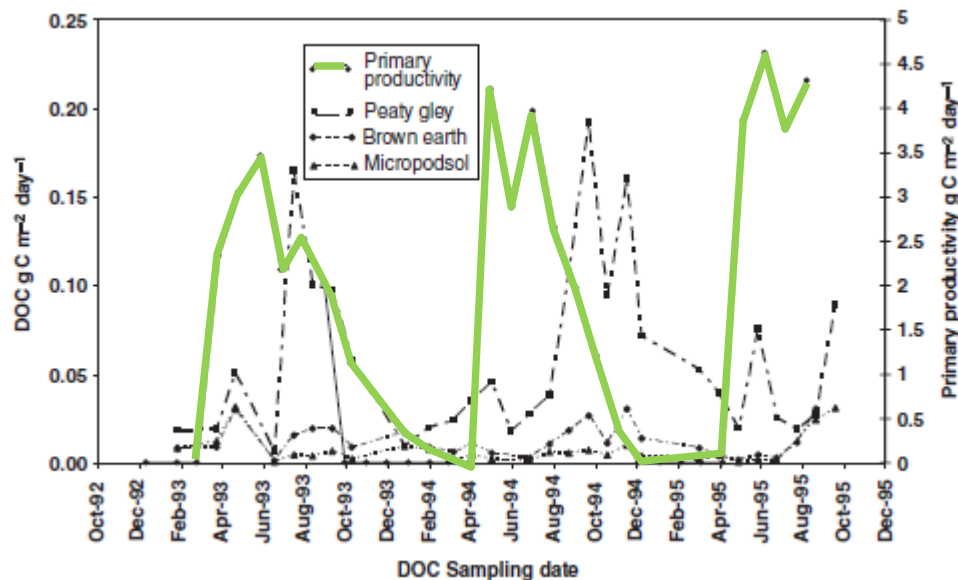

Tipping et al. Biogeochemistry 100, 2010.

so could DOC be used as an indicator of primary productivity both in time and space?

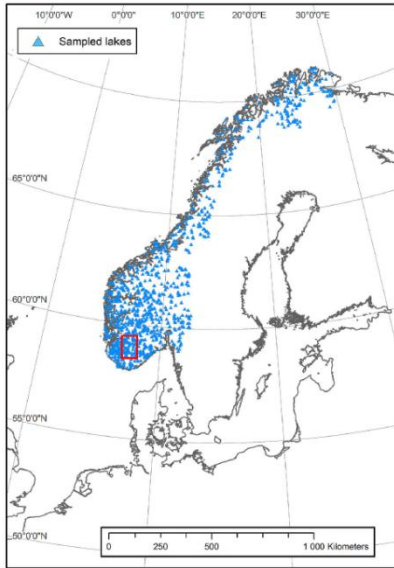

DOC production at Moor House linked to productivity

- Harrison et al., GCB, 2008: - DOC release from Moor House soils manipulation experiments.
- DOC release strongly dependent on current and two-month lagged solar radiation

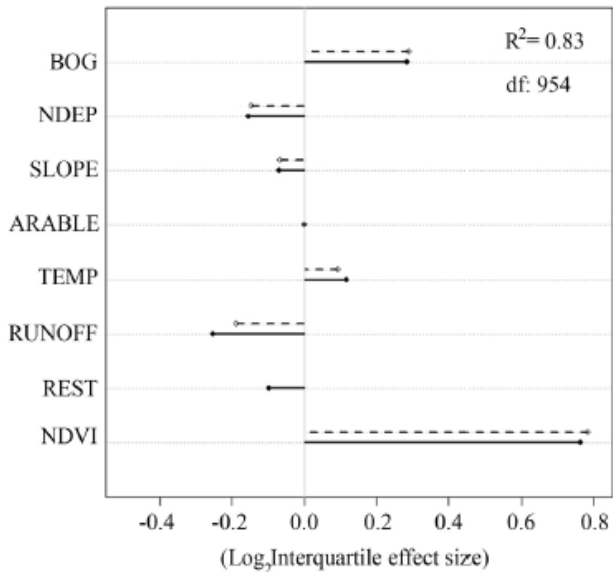

NPP estimate: constant light use efficiency of 0.48 gC MJ⁻¹ when mean monthly temp >6°C

NDVI: “by far the strongest predictor of Norwegian DOC concentrations & fluxes” (attributed to vegetation density)

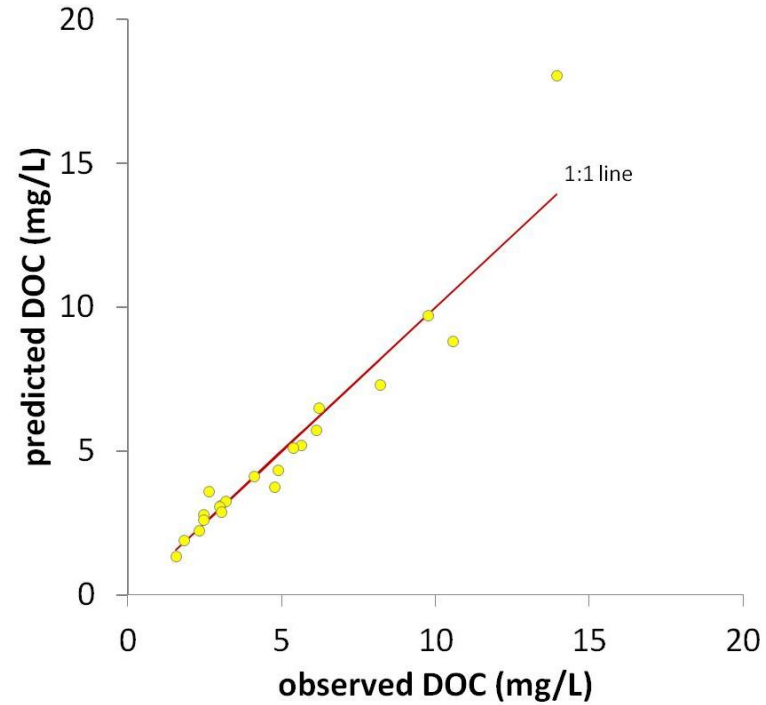

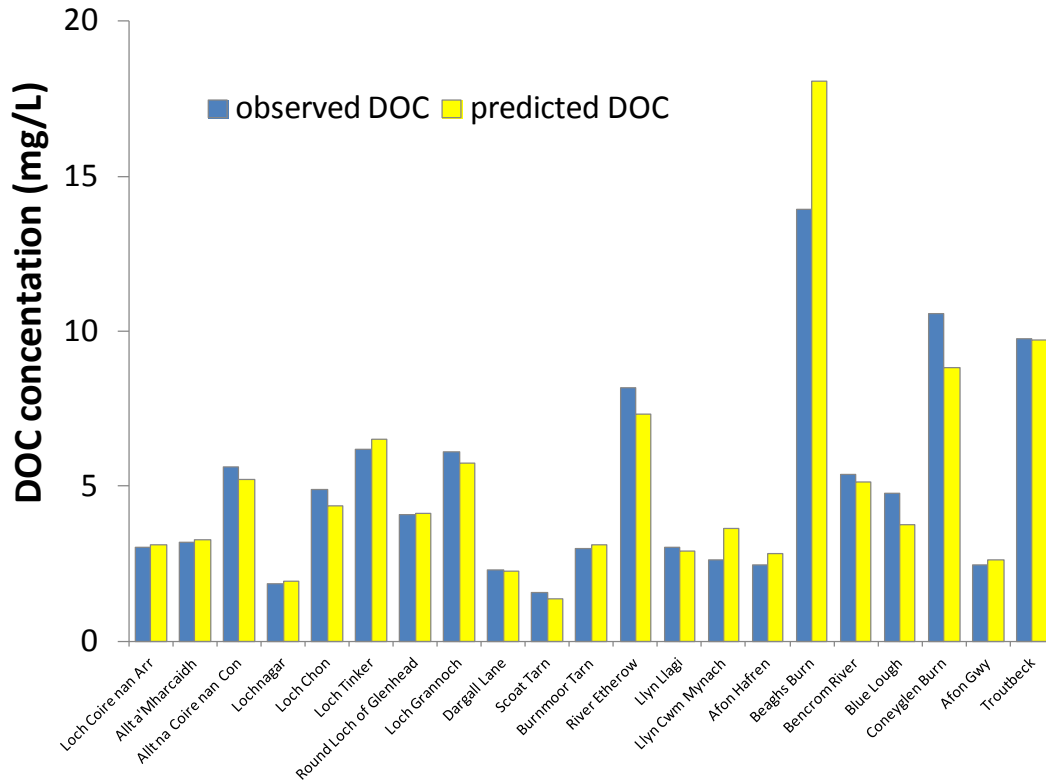

TOC-model

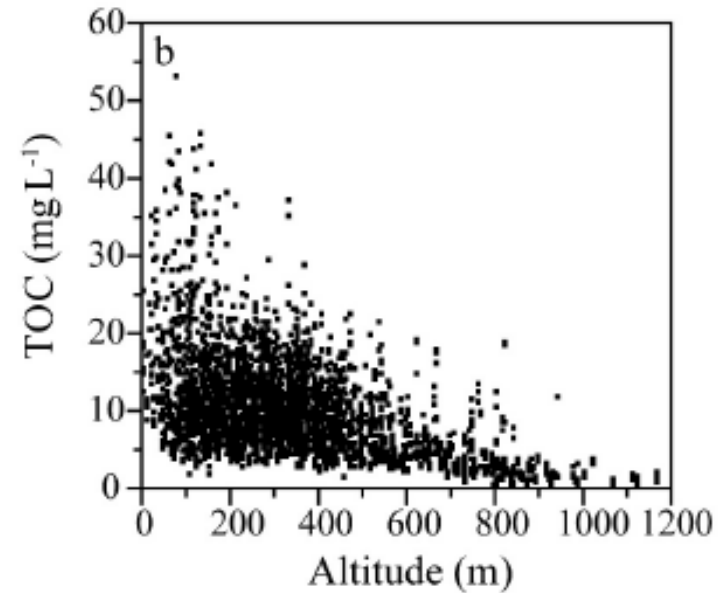

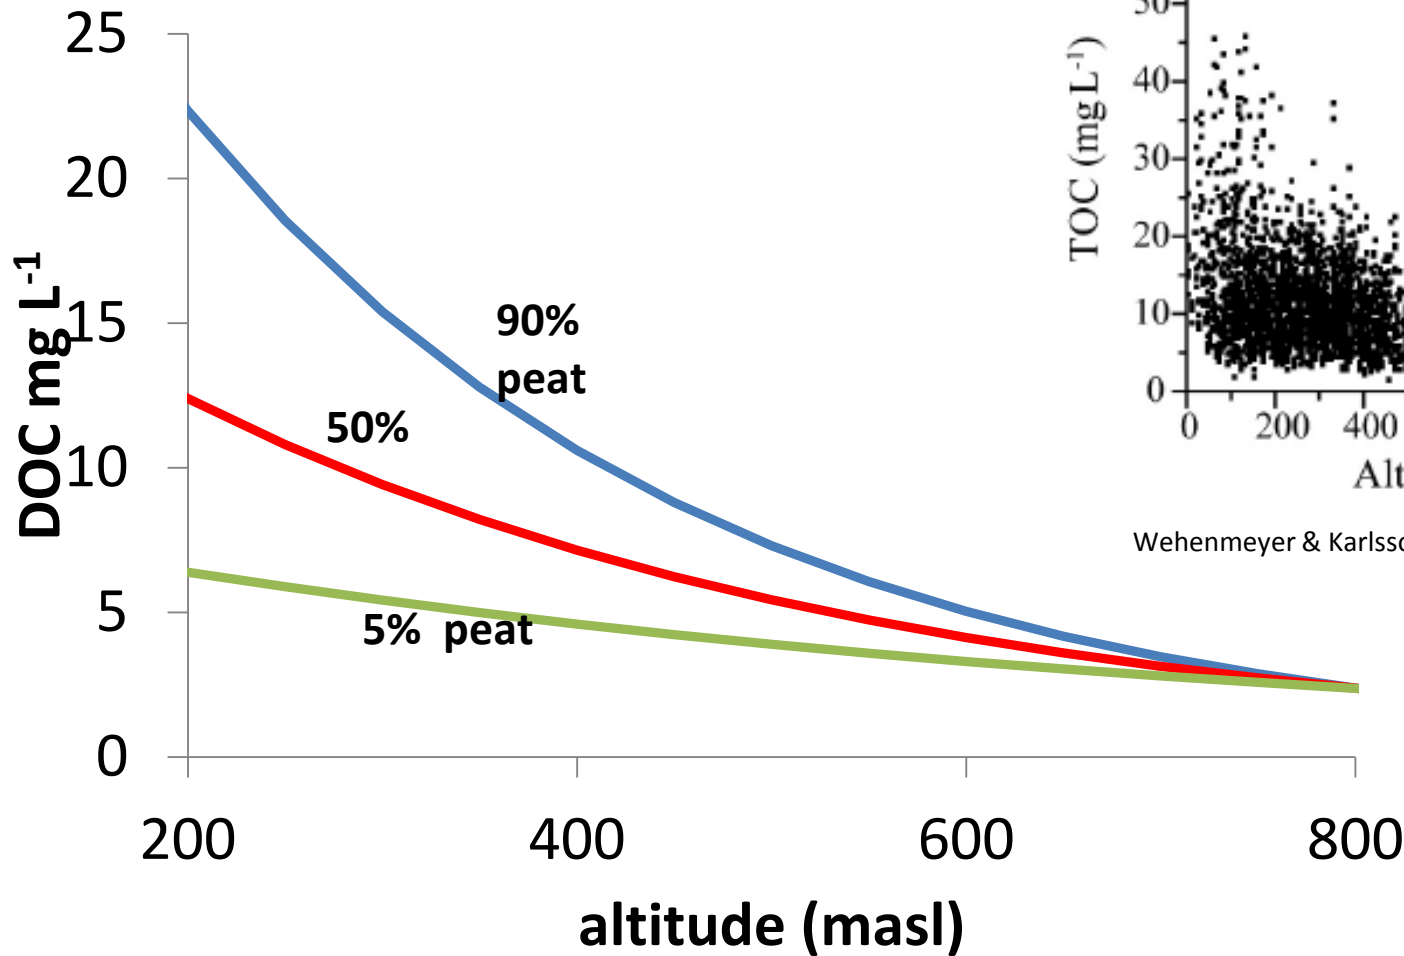

“DOC best explained by the number of days when air temperatures exceeded 0° C, i.e., the duration of the main growing and runoff season”

simple linear model for long term mean concentrations

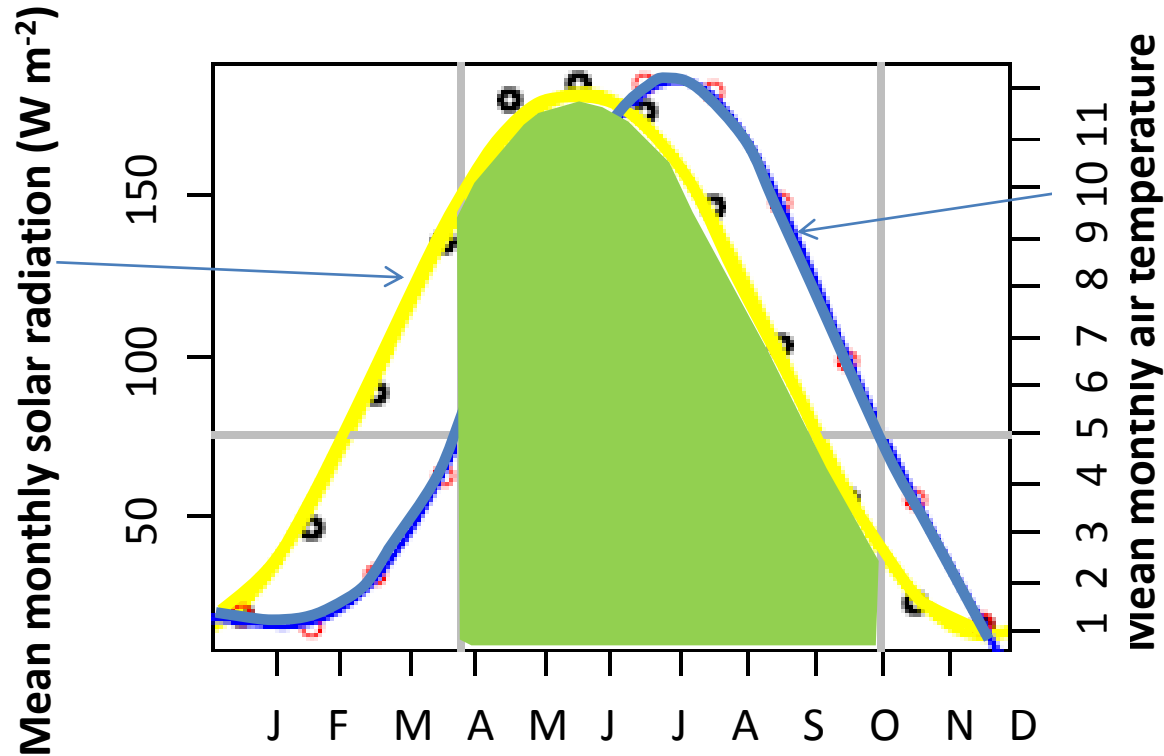

“altitude” major determinant in UK statistical model

Wehenmeyer & Karlsson, 2009. Limnology & Oceanography

Effect of altitude on energy capture during growing season

ECN Moor House meteorology

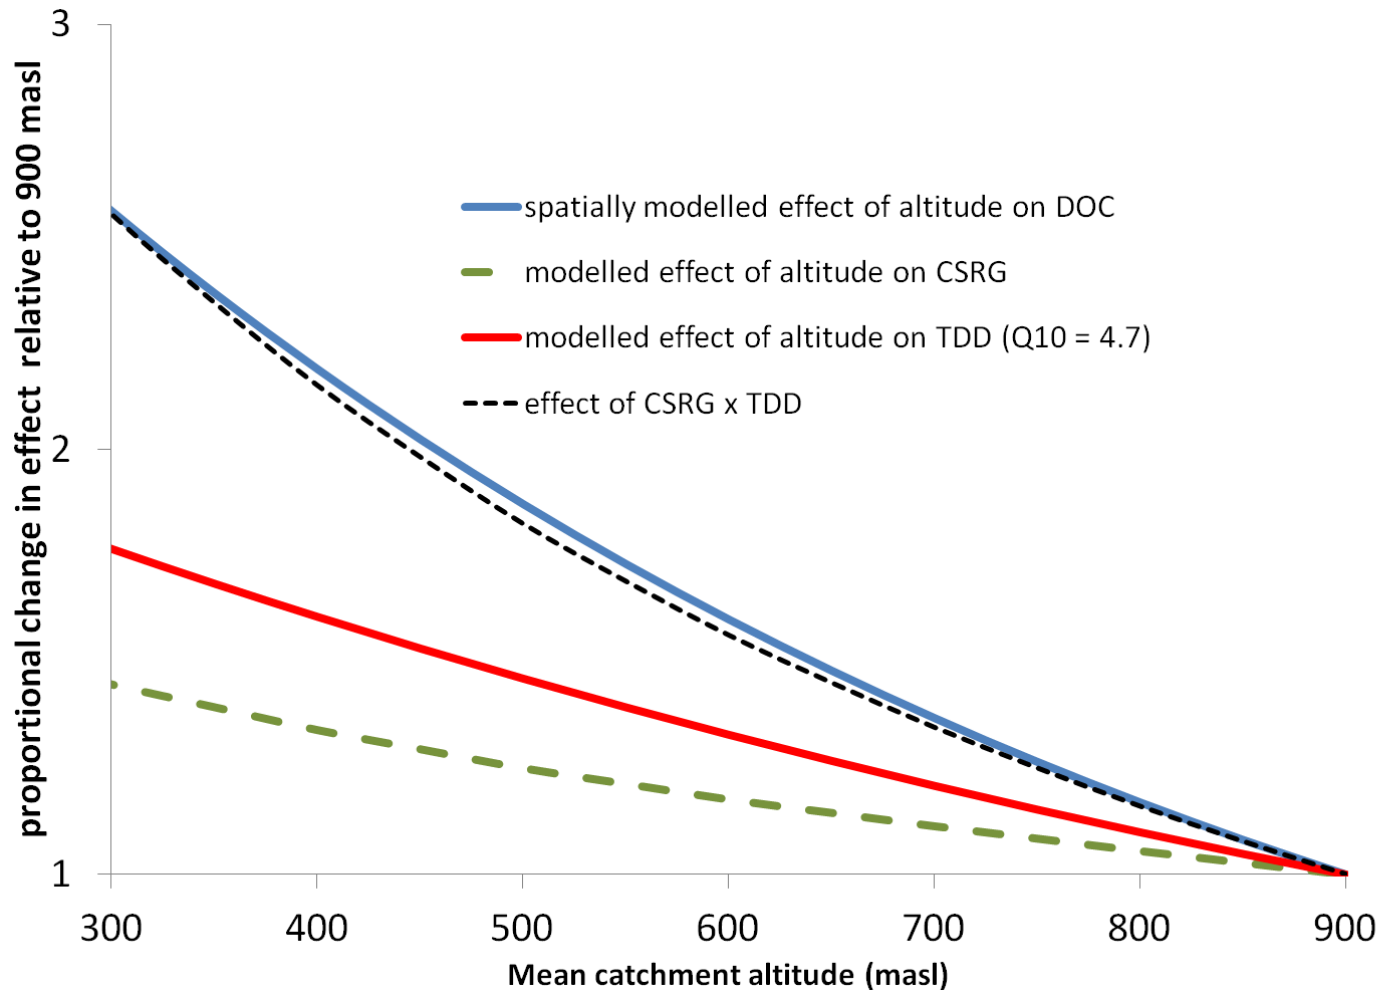

ECN sites used to predict effect of altitude

on cumulative growing season PAR

Response of DOC concentration to altitude explained by combined effects of altitude on cumulative PAR and temperature dependent decomposition (Q10 = 4.7)

Key points:

- DOC concentrations draining upland landscapes appears to be highly predictable
- Reasonable grounds to suspect influence of altitude on DOC export is partly due to effect on NPP – in turn linked to cumulative growing season PAR
- Energetics approach to modelling NPP makes strong mechanistic sense
- Role of water and nutrients as potentially limiting factors can then be described with respect to effect on **light use efficiency**
- Has light use efficiency in the uplands (e.g. Moor House) changed since first estimates made in 1970s?
